Week 2 - questions

- The '=='-operator converts one of the types used in the comparison (if they are not both the same) to compare their contents. The '==='-operator does not, which means that both types in question need to be of the same type.
- Closure is sort of wrapping functions together. This is possible because you can assign a function to a variable, meaning that you can partially fill in a function and then possibly finish it later.
- High order functions are functions to which you can pass another function as a parameter or they return a function themselves
- The query selector function allows you to find certain divs in the html:

```
<script>
function getDiv(d) {
    return document.querySelector(d);
}
</script>
```
